13. ABSTRACT (Maximum 200 words) A method of fitting vapor pressure temperature data to the Antoine equation is described along with a detailed statistical analysis of the fits and calculations of vapor pressures, enthalpies of vaporization, volatilities (concentration of saturated vapors), and boiling points with the Antoine constants. It is shown that the number of digits required to accurately perform vapor pressure calculations is greater than previously believed. The system permits calculation of the limits of error for any level of confidence. A program is used to analyze and plot the available vapor pressure data for diethyl malonate.

PREFACE

The work described in this report was authorized under Project No. 1L162706A553L, Toxin Defense Technology. This work was started in March 1969 and completed in May 1992.

The use of trade names or manufacturers' names in this report does not constitute an official endorsement of any commercial products. This report may not be cited for purposes of advertisement.

Reproduction of this document in whole or in part is prohibited except with permission of the Commander, U.S. Army Chemical Research, Development and Engineering Center (CRDEC), ATTN: SMCCR-SPS-T, Aberdeen Proving Ground, MD 21010-5423. However, the Defense Technical Information Center and the National Technical Information Service are authorized to reproduce the document for U.S. Government purposes.

This report has been approved for release to the public.

Acknowledgments

Special thanks are due to Corkey Smith and Patsy A. D'Eramo, Jr., of the Information Services Division, Management Information Systems Directorate, CRDEC, for their extensive help in locating reports and information. The comments of Dr. Kenneth Collins, Helen M. Walker, and Ann Brozena of the Physical Chemistry Branch, Chemical Division, Research Directorate, CRDEC, are also greatly appreciated. The suggestions of Mary Carroll Croarkin, Statistical Engineering Division, National Institute of Standards and Technology, are greatly appreciated. Thanks are due to Ronald J. Kassel, Organic Chemistry Branch, Chemical Division, Research Directorate, CRDEC, for assistance in obtaining plots.

VAPOR PRESSURE DATA ANALYSIS METHODOLOGY, STATISTICS, AND APPLICATIONS

1. INTRODUCTION

Vapor pressure is one of the most important liquid properties. Vapor pressures have a strong influence on the volatility, reactivity, persistency, toxicity, flammability, solubility, and transfer processes of chemicals. It is a strong function of temperature - increasing from 20 to 1000 ° every ten degrees Celsius. For that reason it is usually plotted against temperature on a logarithmic scale. The slope of a plot of vapor pressures versus temperatures is used to calculate the enthalpy of vaporization which is used to calculate other thermodynamic properties. For such reasons a very precise knowledge of vapor pressures is required for both basic research and practical applications.

Many of the vapor pressure equations or values found in the literature or commercial computerized data bases need to be re-evaluated. Errors run as high as several hundred percent and careful statistical analysis is required.

Decontamination is a typical example of the application of vapor pressure data. In many hazardous chemical situations, there are probably few alternatives other than relying on natural decontamination. Calculations hazardous chemical persistence requires the use of models largely dependent on vapor pressure data. Since tests with hazardous chemicals may not be possible, reliable calculations are essential. Knowledge of the statistical reliability of vapor pressure data permits engineers to include meaningful safety factors in their designs and analyses.

Due to the high cost of experimental measurements, the purpose of this report is to provide a computation method that yields interpolated and extrapolated values of vapor pressure of the maximum accuracy. Also the objective is to provide 95 % or other confidence intervals and other types of statistics for measured, interpolated and extrapolated values of vapor pressures, boiling points, concentration of saturated vapors, and enthalpies of vaporization. Commercial statistical software packages will perform some of the operations included in this effort, but such packages will not include all the detailed calculations provided here. Furthermore, the detailed, referenced, and complete documentation included here is not provided in most software packages. In addition, this report includes software and plotting compatible with currently available DOS based PCs. Diethyl malonate (DEM) vapor pressure data is used to demonstrate the method.

2. BACKGROUND

2.1 Estimation Methods for the Vapor Pressures of Complex Organic Compounds.

Banerjee, Howard, and Lande,¹ describe a structure-vapor pressure relationship for complex organic compounds that probably is one of the best methods available. Their relationship is based on the following type of parameters: Kamlet-Taft solvatochromic, structural, molecular volume, and UNIFAC. The type of errors in the Banerjee, Howard, and Lande method are given in table 1.

Table 1. Accuracy of the Vapor Pressure Estimation Method of Banerjee, Howard, and Lande.

Compound	% Difference Between Experiment and Calculation
<u>Outliers</u>	
octamethyltetrasiloxane	4,800,000%
ethylene glycol	15,500
hexamethyldisiloxane	11,000
acetic acid	2,137
propionic acid	1,950
diisopropyl ether	1,820
1,1,1-trichloroethane	1,740
hexane	1,300
formic acid	1,200
<u>Typical Errors</u>	500-1,100%

Table 1 illustrates the fact that to obtain data sufficiently accurate for most practical purposes, it is necessary to make at least some measurements at a few temperatures.

2.2 The Antoine Equation.

The Antoine equation² is given in equation 1.

$$\log_{10}P = A - B/(t + C) \quad (1)$$

where

P = vapor pressure in Torr*
t = temperature in °C
A, B, C = constants

For many reasons listed in table 2, the Antoine equation has been selected as the equation of choice for fitting most vapor pressure data.

Table 2. The Advantages and the Disadvantages of the Antoine Equation

Disadvantages

- There is no rigorous theoretical basis for the Antoine equation. (There is no rigorous theoretical basis for any tolerably simple vapor pressure-temperature equation useful for fitting and extrapolating data.)
 - It is inadequate for high precision data over the temperature range from the triple point to reduced pressures of 0.75.
-

Advantages

- It requires only three constants.
 - It is quite similar to the Clausius-Clapeyron equation which has an accepted theoretical basis.
 - Temperature may be made the dependent variable by a rudimentary inversion.
 - Extrapolations and interpolations with the Antoine equation are strikingly more trustworthy than most other equations.
 - It may be effortlessly transformed to a linear equation.
 - Is the most widely employed equation for fitting vapor pressure measurements.
-

* Appendix A provides a glossary of terms used in this report.

If X_i and Y_i are defined as follows in equations 2 and 3, the Antoine equation can be transformed into a linear equation (equation 4).

$$X_i = -1/(t_i + C) \quad (2)$$

$$Y_i = \log_{10} P_i = \log_e P_i / \log_e 10 \quad (3)$$

$$Y_i = a_0 + a_1 X_i \quad (4)$$

a_0 and a_1 are constants.

The author and Leo Latour, CRDEC, developed a technique to determine the constants of the linear form of the Antoine equation with a procedure of search by golden section. The method was programmed in FORTRAN to run on a interactive computer with a Typagraph plotter. Since the method was developed in 1971, the program was adapted to several different computer systems at CRDEC. The longest lasting arrangement was with a Unisys 1100/Calcomp plotter system which is scheduled to be removed from service in September 1992. The most recent effort to improve and adapt the program to new computers was performed by Kenneth Collins of CRDEC in 1989. He developed a personal computer version of the program in BASIC and he modified it to be menu driven. No statistics were added by Collins.

The above described software systems have numerous deficiencies that are listed in Table 3.

Table 3. Deficiencies of Currently Available Software

■ The number of digits of accuracy required to perform the computation is not calculated. The number of digits required appears to vary from data set to data set. As a result, computer round off error may have a significant effect on the results in some cases.

■ In the least squares minimization procedure, more than one minimum may exist that goes undetected.

■ Very little statistics is provided. No calculations of 95 % or other confidence limits of boiling points, vapor pressures, volatilities, or enthalpies of vaporization are given. Some of these limits change drastically with temperature and are essential in utilizing the data for practical applications.

■ Methodology and references are not kept with each data point. Keeping methodology and references with each data point aids in the analysis of the data.

■ No standard deviations of the Antoine constants are provided.

■ No correlation coefficient is provided.

■ Data editing is difficult.

■ Plotting does not include 95 % or other confidence limit envelopes.

■ The computer that it is written for, the UNISYS 1100, is being removed from service.

2.3 Least Squares Fits.

The statistical treatment used in this report follows references 3 and 4. A linear equation, equation 4, to predict points randomly distributed about a line, is given as follows:

$$Y_i = a_0 + a_1 X_i \quad (5)$$

Summing over all N observed points, yields equation 6.

$$\sum_{i=1, N} Y_i = N a_0 + a_1 \sum_{i=1, N} X_i \quad (6)$$

Dividing equation 6 by N produces equation 7.

$$1/N \sum_{i=1, N} Y_i = a_0 + a_1/N \sum_{i=1, N} X_i \quad (7)$$

To simplify the following analysis, one may let the sums equal S_1, S_2, S_3, S_4 , and S_5 as ensues:

$$S_1 = \sum_{i=1, N} X_i \quad (8)$$

$$S_2 = \sum_{i=1, N} X_i^2 \quad (9)$$

$$S_3 = \sum_{i=1, N} X_i Y_i \quad (10)$$

$$S_4 = \sum_{i=1, N} Y_i \quad (11)$$

$$S_5 = \sum_{i=1, N} Y_i^2 \quad (12)$$

The means of X_i and Y_i values are found as follows in equations 13 and 14.

$$\text{Mean of } X_i = \bar{X}_i = 1/N \sum_{i=1, N} X_i = S_1/N \quad (13)$$

$$\text{Mean of } Y_i = \bar{Y}_i = 1/N \sum_{i=1, N} Y_i = S_4/N \quad (14)$$

Substituting the mean values from equations 13 and 14 into equation 7 leads to equations 15 and 16.

$$\bar{Y}_i = a_0 + a_1 \bar{X}_i \quad (15)$$

$$S_4 = N a_0 + a_1 S_1 \quad (16)$$

The sum, S , of the squared deviations of the calculated Y_i values subtracted from measured values squared is given by equation 17.

$$S = \sum_{i=1, N} (Y_i - a_0 - a_1 X_i)^2 \quad (17)$$

Squaring the term in parenthesis in equation 17, substituting values from equations 8 to 12, and combining terms yields equations 18 and 19.

$$S = S_5 + N a_0^2 - 2 a_0 S_4 - 2 a_1 S_3 + 2 a_0 a_1 S_1 + a_1^2 S_2 \quad (18)$$

$$a_1 = (N S_3 - S_1 S_4) / (N S_2 - S_1^2) \quad (19)$$

Equation 16 rearranges to equation 20.

$$a_0 = (S_4 - a_1 S_1) / N \quad (20)$$

Equations 18, 19, and 20 permit the easy calculation of S , a_1 , and a_0 , respectively.

The computer program as developed by the author and Latour varied C and recalculated S until a minimum S was located. Since S represents the difference between calculated and measured values, the C that gave the minimum S was the chosen C. Once C was chosen, a_1 and a_0 were calculated with equations 19 and 20

respectively. The differences in logarithms of vapor pressures as opposed to vapor pressures were minimized to get the fit. Otherwise, the lower values of vapor pressure are ignored by the fitting procedures.

2.4 Statistics of Data Fitted to a Linear Equation.

Natrella³ defines a number of statistical quantities as follows:

$$\text{Variance} = V_a = S/(N-2) \quad (21)$$

$$\text{Standard deviation of Y over all X's} = \sigma_{Y_i} = V_a^{1/2} \quad (22)$$

D is defined by equation 23.

$$D = N S_2 - S_1^2 \quad (23)$$

$$\text{Standard deviation of slope} = (V_a N/D)^{1/2} \quad (24)$$

$$\begin{array}{l} \text{Standard deviation} \\ \text{of intercept} \end{array} = [V_a (1.0 + S_1^2/D)/N]^{1/2} \quad (25)$$

Correlation coefficient is the square root of the fraction of the squared variation that is explained by the fit to the data.

$$\text{Correlation coefficient} = (1-S/S_0)^{1/2} \quad (26)$$

where

$$S_0 = \sum_{i=1, N} (Y_i - \bar{Y})^2 \quad (27)$$

The variation of the standard deviation of Y_i with X_i and the F-distribution are discussed in reference 4 and Appendix B, respectively. The F-distribution is used to calculate the limits of error at the 95 % or some other confidence level.

2.5 Enthalpy of Vaporization.

The relation of the enthalpy of vaporization (or evaporation) to other variables is usually expressed as the Clapeyron-Clausius equation⁵ (equation 28).

$$\frac{dP}{dT} = \frac{\Delta H_v}{T \Delta V_t} \quad (28)$$

where

T = temperature in Kelvin

ΔH_v = enthalpy of vaporization

ΔV_t = increase in liquid volume on evaporation
at temperature t

If the Antoine equation, equation 1, is differentiated with respect to T and substituted into equation 28, the following equation results:

$$\frac{dP}{dT} = \frac{PB \log_{10}}{(C+t)^2} = \frac{\Delta H_v}{T \Delta V_t} \quad (29)$$

where

$$\Delta V_t = V(\text{vapor}) - V(\text{liquid})$$

In order to compare the two terms, $V(\text{vapor})$ and $V(\text{liquid})$, the "ideal gas law" is introduced.⁵ The "ideal gas law" that follows is applicable to vapors at low pressures.

$$PV = nRT$$

where

R = ideal gas law constant
 n = number of moles of vapor
 V = volume of vapor

In order to establish the relative importance of the two terms, $V(\text{vapor})$ and $V(\text{liquid})$, they are calculated below for DEM at 25 °C.

$$\begin{aligned} V(\text{vapor}) &= RT/P \\ V(\text{vapor}) &= 82.05 \times 10^{-6} \text{ atm m}^3/\text{mol} \times 298.15 \text{ K} \times 760 \text{ Torr}/0.2231 \text{ Torr} \\ &= 83.335 \text{ m}^3/\text{mol} \end{aligned}$$

$$\begin{aligned} V(\text{liquid}) &= \text{molar volume} = 160.17 \text{ g/mol}/(1.0350 \text{ g/cc} \times 10^6 \text{ cc/m}^3) \\ &= 0.0001518 \text{ m}^3/\text{mol} \end{aligned}$$

Since the $V(\text{liquid})$ is over 5 orders of magnitude smaller than $V(\text{vapor})$, $V(\text{liquid})$ can be safely ignored in computing ΔH_v . On substituting $V(\text{vapor})$ for ΔV_i in equation 29 and rearranging terms, equation 30 follows:

$$\Delta H_v = \frac{\log_{10} RBT^2}{(C+t)^2} \quad (30)$$

Equation 30 makes it possible to calculate enthalpies of vaporization from the temperature and the Antoine constants.

2.6 Concentration of Saturated Vapor.

Since the early 20-th century, the term "volatility" has been defined as follows by the military of the world (See Appendix C).

$$\text{Volatility} = PM/RT \quad (31)$$

Volatility as thus defined is the *concentration of saturated vapor* as calculated from the following variables:

- P = saturation vapor pressure
- T = absolute temperature in Kelvin
- M = compound molecular weight

It is based on the ideal gas law that is fairly accurate at vapor pressures below one atmosphere in pressure. The units of grams or milligrams per cubic meter have been nearly always used. Since many definitions of volatility appear in the literature, the data should be used with caution. Other definitions of volatility that have been used are given in Appendix C.

3. ANALYSIS

3.1 Errors of Vapor Pressure Calculations.

Since the error is extracted from a fit to various types of data, it is assumed in this analysis that all the error is in the vapor pressure values. The experimental temperature control errors are usually so small relative to other errors that they are not reported. The equation for the propagation of errors in terms of variance of vapor pressures, $\Phi_{P_i}^2$, is equation 32.

$$\Phi_{P_i}^2 = |dP_i/dY_i|^2 \Phi_{Y_i}^2 \quad (32)$$

$\Phi_{P_i}^2$ is a function of X_i , and $\Phi_{Y_i}^2$ is a standard deviation of Y_i that is a function of X_i . Y_i was defined in equation 3.

$$Y_i = \log_{10} P_i \quad (3)$$

Equation 33 is equation 3 rearranged.

$$P_i = 10^{Y_i} \quad (33)$$

Taking the derivative of equation 33 with respect to Y_i yields equation 34.

$$dP_i/dY_i = 10^{Y_i} \log_e 10 = P_i \log_e 10 \quad (34)$$

When equation 34 is substituted into equation 32, equation 35 results.

$$\Phi_{P_i}^2 = (P_i \log_e 10)^2 \Phi_{Y_i}^2 \quad (35)$$

with X_1 .⁴ Equation 36 is used to vary the standard deviation

$$\Phi_{Y_1}^2 = \sigma_{Y_1}^2 \left[1/N + \frac{(X_1 - S_1/N)^2}{(S_2 - S_1^2/N)} \right] \quad (36)$$

σ_{Y_1} is calculated from equation 22. The error in vapor pressure is given by equation 37.

$$\begin{array}{l} \text{Error in vapor pressure} \\ \text{at a given temperature} \end{array} = \pm (3F)^{1/2} \Phi_{P_1} \quad (37)$$

The value, F , is the percentile value of the F -distribution for the selected confidence level. Appendix B explains how F is calculated at any confidence level.

3.2 Errors of Boiling Point Calculations.

Equation 1, the Antoine equation,

$$\log_{10} P_1 = A - B / (t + C) \quad (1)$$

may be rearranged to provide the boiling point, t_b , as in equation 38.

$$t_b = B / (A - \log_{10} P_1) - C \quad (38)$$

The variance of the boiling point, $\sigma_{t_b}^2$, is calculated with equation 39.

$$\sigma_{t_b}^2 = |\delta t_b / \delta P_1|^2 \Phi_{P_1}^2 \quad (39)$$

Taking the derivative of equation 38 with respect to P_1 yields equation 40.

$$\delta t_b / \delta P_1 = B(A - \log_{10} P_1)^{-2} (P_1 \log_e 10)^{-1} \quad (40)$$

On substituting equation 40 into equation 39 and taking the square root yields a standard deviation for the boiling point, σ_{t_b} .

$$\sigma_{t_b} = B(A - \log_{10} P_1)^{-2} (P_1 \log_e 10)^{-1} \Phi_{P_1} \quad (41)$$

On substituting equation 35 into equation 41, equation 42 results when P is set at 760 Torr, the vapor pressure at the boiling point under standard conditions.

$$\sigma_{t_b} = B(A - \log_{10} 760)^{-2} \sigma_{Y(760)} \quad (42)$$

$\sigma_{Y(760)}$ is the standard deviation of Y at 760 Torr.

The error in the boiling point is given by equation 43.

$$\text{Error in boiling point} = \pm (3F)^{1/2} \sigma_{t_b} \quad (43)$$

F is the percentile values of the F -distribution for the the selected confidence level. Appendix B explains how F is calculated at any confidence level.

3.3 Errors in Enthalpy of Vaporization Calculations.

The enthalpy of vaporization may be computed by starting with equation 30.

$$\Delta H_v = RB \log_{10} [(t_1 + 273.15)/(t_1 + C)]^2 \quad (30)$$

The variance of the enthalpy of vaporization is calculated with the following propagation of errors equation:

$$\Phi_{\Delta H_v}^2 = \left| \frac{\delta \Delta H_v}{\delta t_1} \right|^2 \left| \frac{\delta t_1}{\delta P_1} \right|^2 \Phi_{P_1}^2 + \left| \frac{\delta \Delta H_v}{\delta B} \right|^2 \sigma_B^2 + \left| \frac{\delta \Delta H_v}{\delta C} \right|^2 \sigma_C^2 \quad (44)$$

Taking the partial derivative of ΔH_v in equation 30 with respect to t_1 yields equation 45.

$$\left(\frac{\delta \Delta H_v}{\delta t_1} \right)_{B,C} = -2RB \log_e 10 \frac{(t_1 + 273.15)(C - 273.15)}{(t_1 + C)^3} \quad (45)$$

Taking the partial derivative of ΔH_v in equation 30 with respect to B yields equation 46.

$$\left(\frac{\delta \Delta H_v}{\delta B} \right)_{t_1,C} = R \log_e 10 \left[\frac{t_1 + 273.15}{t_1 + C} \right]^2 \quad (46)$$

Taking the partial derivative of ΔH_v in equation 30 with respect to C yields equation 47.

$$\left(\frac{\delta \Delta H_v}{\delta C} \right)_{t_1,B} = -2RB \log_e 10 \frac{(t_1 + 273.15)^2}{(t_1 + C)^3} \quad (47)$$

Taking the partial derivative of t_1 in equation 30 with respect to P_1 yields equation 48:

$$\left(\frac{\delta t_1}{\delta P_1} \right)_{A,B} = -B(A - \log_{10} P_1)^{-2} (P_1 \log_e 10)^{-1} \quad (48)$$

Substituting equations 45-48 into equation 44 yields equation 49.

$$\begin{aligned} \Phi_{\Delta H_v}^2 = & \left| 2RB^2 \frac{T(C-273.15)}{(t+C)^3 (A - \log_{10} P_1)^2 P_1} \right|^2 \Phi_{P_1}^2 + \\ & \left| R \log_e 10 \frac{T^2}{(t+C)^2} \right|^2 \sigma_B^2 + \\ & \left| 2RB \log_e 10 \frac{T^2}{(t+C)^3} \right|^2 \sigma_C^2 \end{aligned} \quad (49)$$

The error in the enthalpy of vaporization at a given temperature is furnished by equation 50.

$$\begin{aligned} & \text{Error in the enthalpy of} \\ & \text{vaporization at a given} = \pm (3F)^{1/2} \Phi_{\Delta H_v} \\ & \text{temperature} \end{aligned} \quad (50)$$

3.4 General Computation Methodology.

The computation is performed differently from previous methods. First a series of values of C are used to calculate a series of S values. Then the S values are searched for minimums and maximums to see if there is more than one minimum. Then the C values are fine tuned to give the C that yields the minimum S. The C that yields the minimum S is then used to calculate the other Antoine constants and the statistics. No effort is made to use an optimized search strategy to conserve computer time since the running time is less than 2 minutes on a Swan Technologies 386/33.

3.5 The Computer Program.

The program used is named "ANT592.BAS" and is written in MS-DOS GW-BASIC for IBM compatible personal computers. The methods of indexing organic compounds and abbreviating references used in the program are given in Appendices D and E respectively. Concentrations of saturated vapor or volatilities (Appendix C) are calculated as a function of temperature. Definitions of the terms used in the program are given in appendix F. The program is listed in Appendix G. When vapor pressure points are entered, an experimental method by which they were obtained and a reference is entered at the same time. The numbers used to represent each method are given in table 4. The data is entered into a BASIC file to preserve the editing capabilities of either GW-BASIC, QBASIC, or any editor that can create a DOS file. The data input format is given in Appendix H.

"ANT592.BAS" produces a "command file" ("ANTPLT.PLT") which includes the data for plotting plus detailed plotting directions. "ANT592.BAS" gives the user a number of options in creating the "command file." After "ANT592.BAS" is run, the user must terminate GW-BASIC with a "SYSTEM" command and switch to "ProPLOT" software. In "ProPLOT" the user may view the plots on the screen before plotting, edit the plots, and send them to a laser printer. "ProPLOT" is a 2-D scientific plotting software package sold by Cogent Software that creates PostScript printer output.

Table 4. The Numbers Used to Represent Each Experimental Method.

<u>Number</u>	<u>Method</u>
1	Isoteniscope
2	Boiling Point

6	Tensimeter
7	Gas Chromatography
8	DTA
9	Ebulliometry
10	Calculated
11	Method Not Given
12	Droplet Evaporation

4. RESULTS

A sample calculation for DEM is provided in Appendix I.

Brozena and Fielder's⁶ data for DEM was chosen to demonstrate the methodology. As is apparent from Appendix I, the fit is good and there are more statistically significant digits, three, available than is normally expected from vapor pressure data. At least three digits for the enthalpy of vaporization are significant and four should be reported. The error estimation techniques used are worst case methods; they are so inclusive that errors are probably over-estimated.

Figure 1 shows that a plot of logarithm of vapor pressure versus $-1/(t+C)$ which gives a very linear plot of the data. The data fits the Antoine equation fit so well that the error bars are expanded 20 times the actual error limits to permit their being easily observable. Clearly the DEM data is excellent. Figures 2-6 provide simple vapor pressure versus temperature plots with error bars.

The program "ANT592.BAS" takes about 20 minutes running time more or less on a number of early model IBM compatible PCs, but on a Swan 386/33 it runs in minute or so. The program has estimated that ten decimal digits accuracy is required for the DEM data set.

Figure 1. Comprehensive Plot of Logarithm of Vapor Pressure Versus $-1/(t+C)$

Figure 2. Vapor Pressure Versus Temperature Plot from 0.01 to 0.1 Torr

Figure 3. Vapor Pressure Versus Temperature Plot from 0.1 to 1.0 Torr

Figure 4. Vapor Pressure Versus Temperature Plot from 1.0 to 10. Torr

Figure 5. Vapor Pressure Versus Temperature Plot from 10.0 to 100. Torr

Figure 6. Vapor Pressure Versus Temperature Plot from 100. to 1000. Torr

5. DISCUSSIONS

In MS-DOS GW-BASIC for IBM compatible personal computers, single precision goes from 10^{-38} to 10^{+38} with 6 decimal digits and double precision covers the same range with 16 decimal digits. The program calculates the number of digits required to avoid significant round off errors. Since twelve digits were required for the DEM data given in this report and as many as 14 digits with other sets of data were required, double precision is definitely necessary for an Antoine fit.

Statistical error analysis is often a much larger task than making measurements and analyzing the data without statistics.

In addition to being used to fit vapor pressure data, the Antoine may be used to fit densities, fugacities of liquids, viscosities, relative vapor pressures, and other types of data. The only time that the program was found to give more than one minimum was when it was run in the single precision mode.

The analysis performed in this report shows that Brozena and Fielder's⁸ data for DEM is one of the best series of vapor pressure data found anywhere in the scientific literature.

6. CONCLUSIONS

■ The program "ANT592.BAS" performs all the calculations of previous programs satisfactorily, plus it provides detailed statistical analysis and error envelopes for any confidence level for vapor pressures, enthalpies of vaporization, concentrations of saturated vapor, and boiling points.

■ More statistically significant decimal digits are available for vapor pressure data, three, than has been previously believed. In the future four digits should be published.

■ Five decimal digits for the enthalpy of vaporization values are significant and should be reported.

■ Double precision computations (10-16 decimal digits) are required for maintaining the full significance of carefully measured vapor pressure data.

■ The ANT592.BAS"/"ProFLOT" system produces greatly improved plots with error limits.

APPENDIX A

GLOSSARY OF TERMS

A	= constant for the Antoine equation, equation 1
a_0	= intercept in equation 4
a_0	= slope in equation 4
B	= constant for the Antoine equation, equation 1
C	= constant for the Antoine equation, equation 1
D	= value defined by equation 23
F	= percentile value of the F-distribution for the selected confidence level
ΔH_v	= enthalpy of vaporization
M	= molecular weight of vapor
N	= number of observed points
n	= number of moles of vapor
P	= vapor pressure in Torr
R	= ideal gas law constant
S	= sum of the deviations of the Y values squared, defined by equation 17
S_1	= sum of X_i s, defined by equation 8
S_2	= sum of X_i^2 s, defined by equation 9
S_3	= sum of $X_i Y_i$ s, defined by equation 10
S_4	= sum of Y_i s, defined by equation 11
S_5	= sum of Y_i^2 s, defined by equation 12
S_9	= value defined by equation 27

t	= temperature, °C
T	= temperature in Kelvin
t_b	= boiling point, °C
V	= volume of vapor
V_s	= variance of Y_i s
ΔV_i	= Change in volume of a given amount of fluid on evaporation at a given temperature and pressure
X_i	= $-1/(t_i + C)$
\bar{X}_i	= mean of X_i s
Y_i	= $\log_{10} P_i$
\bar{Y}_i	= mean of Y_i s
σ_B	= standard deviation of B
σ_C	= standard deviation of C
$\sigma_{\Delta H_v}$	= standard deviation of enthalpy of vaporization
σ_{t_b}	= standard deviation of boiling point
σ_{Y_i}	= standard deviation of Y_i s
$\phi_{\Delta H_v}$	= standard deviation of enthalpy of vaporization that is a function of t
ϕ_{P_i}	= standard deviation of vapor pressures that is a function of t
ϕ_{Y_i}	= standard deviation of Y_i that is a function of the size of X_i or t_i .

APPENDIX A

APPENDIX B

CALCULATION OF F FROM F-DISTRIBUTION

Equation 1 provides the equation that is integrated to the required level of confidence to obtain the standard statistical value, F.¹

$$f(F) = \int_0^F \left[\frac{\Gamma\left(\frac{u+v}{2}\right) u^{\frac{u}{2}} v^{\frac{v}{2}} F^{\frac{u}{2}-1} (v+uF)^{-\frac{u+v}{2}}}{\Gamma\left(\frac{u}{2}\right) \Gamma\left(\frac{v}{2}\right)} \right] dF \quad (1)$$

where:

$f(F)$ = F-distribution
 Γ = gamma functions
 u = degrees of freedom in the numerator of F
 v = degrees of freedom in the denominator of F

The gamma function, Γ , was calculated with the following equation:²

$$\log_e \Gamma(x) = \left(x - \frac{1}{2}\right) \log_e x - x + \frac{1}{2} \log_e (2\pi) + \frac{1}{12x} - \frac{1}{360x^3} + \frac{1}{1260x^5} - \frac{1}{1680x^7} \quad (2)$$

where x is the argument of the gamma function.

For the calculations for errors in this report v is taken as the number of points minus three and u is taken as three.

APPENDIX C

DEFINITION OF VOLATILITY OR CONCENTRATION OF SATURATED VAPOR

Parker¹ claims volatility is a thermodynamic quantity with the following qualitative definition: "The quality of having a low boiling point or subliming temperature at ordinary pressure or equivalently, of having a high vapor pressure at ordinary temperatures."

According to Bridgeman² of the National Bureau of Standards the "volatility of gasoline is the temperature at which a given air-vapor mixture is formed under equilibrium conditions at a pressure of one atmosphere, when a given percentage is evaporated."

The Kirk-Othmer Encyclopedia of Chemical Technology³ deals with volatility as follows. "The volatility of kerosine fuel is measured not by its vapor pressure but by its temperature at the point where its vapors prove to be flammable, ie, the flash point or lean flammability temperature."

Some reports seem to use the Reid vapor pressure as a measure of volatility. It is defined by the U.S. Coast Guard⁴ as the equilibrium vapor pressure exerted by vapor over the liquid at 100 °F., expressed as pounds per square inch absolute, as defined by the 46 Code of Federal Regulations 30.10-59.

The United Nations⁵ defined volatility as the concentration of saturated vapor at 20 °C in units of mg/m³. This the standard definition used by the military of most nations, but the U.S. Coast Guard⁴ refers to this quantity as the saturated vapor density.

Volatility has been historically defined as follows by the U.S. Department of Defense:

$$\text{Volatility} = PM/RT$$

This is the concentration of vapor as calculated from the vapor pressure, P, and the absolute temperature, T. It is based on the ideal gas law that is fairly accurate at vapor pressures below one atmosphere in pressure. The units of grams or milligrams per cubic meter have always been used.

Since the term volatility has multitude of definitions in the literature, it is recommended that "volatility" not be used by the U.S. Army in the future and the term "concentration of saturated vapor" at a given temperature be used instead. The units should remain grams or milligrams per cubic meter.

APPENDIX D

EMPIRICAL FORMULA INDEXING OF ORGANIC COMPOUNDS

Generally the simplest way to index organic compounds is a empirical formula index (better named an elemental formula). This index that is usually used to locate compounds is given as follows:

where

- C = Carbon
- n = Number of carbon atoms in molecule
- H = Hydrogen
- m = Number of hydrogen atoms in molecule
- X,Y,Z = Elements other than carbon and hydrogen
 (Usually given in alphabetical order)
- o,p,q = Number of elements other than carbon and
 hydrogen

The elemental formula are listed in alphabetical and numerical order(lower numbers first). Lange's Handbook of Chemistry provides examples.*

* Dean, J.A., Lange's Handbook of Chemistry, 13th ed., McGraw-Hill Book Co., New York, page 7-54, 1985.

Blank

APPENDIX E

CHEMICAL THERMODYNAMICS DATA CENTER (NIST) REFERENCE CODE

The following method of handling references* has been found to be more useful than simply numbering references:

Code: XXAAA/BBB N

where

XX = Last two digits of year

AAA = First 3 letters of the last name of first author

BBB = First 3 letters of the last name of second author

N = Digit from 2 to 9 used to represent a second or third paper of the first and second author in the same year.

Thus 60ADA/BRO 4 would be used to represent the 4-th paper by Adams and Brown in 1960 referenced in the report. 80SMI would represent the only paper by Smith in 1980 referenced in the report.

APPENDIX H

DATA INPUT FORMAT

Line 4000 of Appendix G is the first line of a sample data input. It is recommended that data points be entered in order from low to high temperature. Data points must be stored in a basic file starting with line 4000. Save the file with the 'A' option (SAVE "DATAFILE.BAS",A). To merge with the program and the program (LOAD "ANT592.BAS"), and merge with the data file (MERGE "DATAFILE.BAS"). If the data file is not saved with the "A" option, merging will not be possible. The data is entered into a basic file to preserve the full screen editing capabilities of GW BASIC or QBASIC.

Data is entered in the following order separated by commas:

Experimental formula in quotes,
Number of elements in compound,
Number of data points,
First element symbol in quotes,
Number of atoms of first element,
Second element symbol in quotes,
Number of atoms of second element,

Compound name in quotes,
Boiling point in Celsius,

First data point
Temperature(Celsius), Vapor Pressure (Torr), Reference Code*,
Number for Experimental Method**,

See Appendix E.

See Table 4 in section 3.5 of the report.

{Second data point}

Temperature(Celsius), Vapor Pressure (Torr), Reference Code*,
Number for Experimental Method**,

...
...

{N-th data point}

Temperature(Celsius), Vapor Pressure (Torr), Reference Code*,
Number for Experimental Method**,

* See Appendix E.

** See Table 4 in section 3.5 of the report.

APPENDIX I
SAMPLE COMPUTER RUN

run
ADVANCED VAPOR PRESSURE DATA ANALYSIS AND PLOTTING

PROGRAM: ANT592.BAS
Run date is 06-06-1992
Is 95% confidence level OK? (Y or N) ? y
The 95.0 % confidence level was chosen.
Do you intend to plot? (Y or N) ? n

Element	Atomic Weight	Number	Experimental Method
C	12.01100	1	Isoteniscope
H	1.00790	2	Boiling Point
Br	79.90400	3	Effusion
Cl	35.45300	4	Dynamic Gas Saturation
F	18.99840	5	Manometer
N	14.00670	6	Tensimeter
O	15.99940	7	Gas Chromatography
P	30.97380	8	DTA
S	32.06000	9	Ebulliometry
Si	28.08600	10	Calculated
	0.00000	11	Method Not Given
	0.00000	12	Droplet Evaporation

Elemental Formula = C7H12O4 C 7 H 12 O 4
Calculated Molecular Weight of Diethyl Malonate = 160.1694

Review of Fitting Process

Final C = 223.0810 at an Interval of 0.00135
 Final S = 0.0211210814095 after 16 th step
 Number of digits required in calculation is 12

RESULTS

Antoine Constants for Diethyl Malonate:

A = 8.0005804 B = 2146.40052 C = 223.081

Standard Deviation of A = 0.020955 and of B = 3.200

F = 2.752 at 95.0 % Confidence Level

Standard Deviation of Log(10)P(Torr) = 1.817D-02

Boiling Point = 196.2 +/- 0.8 Celsius

Variance = 3.300E-04

Correlation Coefficient = 0.99993

Number of Points = 66

Melting Point = -48.9 Celsius
